## **STANDARD WARRANTY FOR EG&G/ORTEC INSTRUMENTS**

EG&G/ORTEC instruments are warranted to be free from defects in material and workmanship for **one year** from date of shipment or for the specified period for certain components listed in the operating manual. EG&G/ORTEC will repair or replace, at its option, any product that proves to be defective during the warranty period, provided it has been used in a proper manner. No other warranty is expressed or implied.

EG&G/ORTEC must be informed in writing of the nature of the fault of the instrument being returned and of the model and serial numbers. Failure to do so may cause unnecessary delays in getting the unit repaired. Instruments that are returned should be packed so that they will withstand normal handling and must be shipped **PREPAID** via Air Parcel Post or United Parcel Service to the Customer Service Department, 100 Midland Road, Oak Ridge, Tennessee.

## **QUALITY CONTROL**

Before being approved for shipment, each EG&G/ORTEC instrument must pass a stringent set of quality control tests designed to expose any flaws in materials or workmanship. Permanent records of these tests are maintained for use in warranty repair and as a source of statistical information for design improvements.

Our standard procedure requires that instruments returned for repair pass the same quality control tests that are used for new-production instruments.

## **DAMAGE IN TRANSIT**

Shipments should be examined immediately upon receipt for evidence of external or concealed damage. The carrier making delivery should be notified immediately of any such damage, since the carrier is normally liable for damage in shipment. Packing materials, waybills, and other such documentation should be preserved in order to establish claims. After such notification to the carrier, please notify EG&G/ORTEC of the circumstances so that we may assist in damage claims and in providing replacement equipment if necessary.

## T122/NL QUAD UPDATING DISCRIMINATOR

### 1. CHARACTERISTICS

The T122/NL Quad Updating Discriminator is a direct-coupled lower-level discriminator module containing four identical independent sections with common gating. The T122/NL is packaged as a NIM-standard single-width module per USAEC document TID-20893 (Rev); the resulting high packing density makes it extremely useful in applications requiring many discriminator channels or where NIMBIN® space is limited. In line with the design objective of compacting the circuitry as much as possible, the T122/NL has been designed with LEMO type RA-00-250 front panel connectors, which are considerably smaller than BNC connectors.

A tunnel-diode discriminator with a controlled reset function prevents multiple-firing on wide input signals. The T122/NL produces only one output pulse each time an input pulse exceeds the threshold, no matter how long the input signal remains above the threshold. The tunnel-diode discriminator also provides low time-slewing with excellent threshold stability.

The T122/NL has an updating timer which guarantees that an output signal persists for a preselected time duration after the most recent input threshold crossing, independent of previous operating history.

®Registered trademark of EG&G.

The T122/NL is equipped with a common gate amplifier for the four discriminators. The gating function is controlled by a locking toggle switch located on the rear panel of the module and is initiated by an external NIM-standard slow logic signal. However, for this feature to be utilized, the T122/NL must be installed in a bin that is equipped with logic lines or buses, as well as with power distribution lines or buses. Many bins are equipped with power distribution lines or buses only.

The input threshold level and the output pulse width are continuously variable throughout their respective design ranges by means of recessed front panel potentiometers, and a front panel monitor jack is provided for measuring the threshold level setting.

A normal dual output and a single back-terminated complementary output are provided, giving a fanout of three NIM fast logic signals per section.

Since the T122/NL has the common gating feature and since it makes extensive use of  $\pm 6$ -V power lines, we recommend that it be installed in an EG&G/ORTEC M400 NIMBIN, which in addition to the normal NIM requirements provides  $\pm 6$  V at 8 A and, among others, the logic line required for the common gating feature.

### 2. SPECIFICATIONS

#### 2.1. PERFORMANCE

**Temperature Range** 0 to 50°C.

**Continuous Wave Rate** >100 MHz.

**Pulse Pair Response** Counting, 7 nsec for 2 discrete pulses (typically 50% duty cycle at minimum width); timing, 10 nsec for 0.5-nsec change in timing; updating, for pulse widths >10 nsec, output is present for a time equal to the pulse width setting after the last threshold crossing.

**Threshold** Range, -50 to >-200 mV; monitor calibration, 10 mV = 1 mV threshold; temperature coefficient,

< $\pm 150 \mu\text{V}/^\circ\text{C}$ ; second pulse sensitivity <1-dB change for pulse spacing >9 nsec.

**Output Width** Range, 5 to 800 nsec (typical); other ranges optional; temperature coefficient < $\pm 0.2\%/\text{ }^\circ\text{C}$ .

**Slewing** 1.0 nsec (typical) from threshold (50% triggering probability) to X10 threshold.

#### 2.2. CONTROLS

Note: There is only one Bin Gate switch; the other controls exist in each of the four discriminator circuits.

**Width** Recessed, screwdriver-adjusted, 22-turn, front panel potentiometer adjusts the width of the output pulse throughout the range 5 to 800 nsec.

**Thresh** Recessed, screwdriver-adjusted, 22-turn, front panel potentiometer adjusts the response threshold for input pulses throughout the range -50 to greater than -200 mV.

**Width Cal** Internal screwdriver-adjusted potentiometer calibrates the range of the Width control.

**Thresh Norm** Internal screwdriver-adjusted potentiometer, together with the Thresh Cal control, calibrates the range of the Thresh control.

**Thresh Cal** Internal screwdriver-adjusted potentiometer, together with the Thresh Norm control, calibrates the range of the Thresh control.

**Reset** Internal screwdriver-adjusted potentiometer calibrates the level to which an input signal must decrease for the tunnel-diode discriminator to be reset to its low-voltage state.

**Bin Gate** Rear panel, two-position, SPST, locking toggle switch provides selection of the acceptance or rejection of the bin system gating (inhibit) signal. In the closed (Gated) position the bin system gating signal can get through to the internal circuitry of the module and therefore will prevent all four discriminator circuits from passing any pulses until it is removed or until the switch is opened. In the open (Ungated) position the bin system gating signal cannot get past the switch and therefore cannot affect the internal circuitry of the module in any way. For this switch to be of any use, the module must be installed in a bin that has the necessary logic line or bus to convey the bin system gating signal to every station in the bin from an outside source. Such a bin is the EG&G/ORTEC M350 NIMBIN.

### 2.3. INPUTS

**Input 1–Input 4** LEMO connectors, type RA-00-250, front panel.

**Impedance**  $50\Omega$ .

**Reflections**  $<10\%$  (dc or transient).

**Offset**  $0 \pm 10$  mV.

**Temperature Coefficient**  $-0.1$  mV/ $^{\circ}$ C.

**Protection**  $\pm 300$  V for 1  $\mu$ sec/sec.

**Bin Gate** All sections controlled by a single rear panel toggle switch, which is connected to the bin gating line.

### 2.4. OUTPUTS

**A/B, A** LEMO connectors, type RA-00-250, front panel; pulse width 5 to 800 nsec (typical); other ranges optional.

**Fanout** One dual and one back-terminated complement NIM-standard fast logic signals\* per section.

**Times for  $T_{01}$  and  $T_{10}$**  2.0 nsec (typical).

**Delay** 13 nsec (typical) from threshold crossing to half-amplitude point of output pulse.

### 2.5. ELECTRICAL AND MECHANICAL

#### Power Required

+24 V, 73 mA; -24 V, 0 mA;  
+12 V, 154 mA; -12 V, 150 mA;  
+ 6 V, 44 mA; - 6 V, 300 mA.

**Dimensions** NIM-standard single-width module (1.35 by 8.714 in.) per TID-20893 (Rev).

**Panel Color** Black.

\*Zero =  $0 \pm 50$  mV; one =  $-800 \pm 100$  mV;  $T_{01}$  denotes zero-to-one transition;  $T_{10}$  denotes one-to-zero transition.

## 3. APPLICATIONS

### 3.1. GENERAL

The T122/NL Quad Updating Discriminator is a direct-coupled lower-level discriminator module containing four identical independent sections with common gating. Packaged as a NIM-standard single-width module, per USAEC document TID-20893 (Rev), the T122/NL is designed for low-cost-per-channel applications in which many discriminators are required or where NIMBIN space is severely limited or restricted. It is designed to process fast negative-going linear signals such as those produced at a photomultiplier anode, and can also be used to regenerate logic

signals that have been attenuated by transmission over long cable runs.

Each section has a tunnel-diode discriminator with a controlled reset function to prevent multiple-firing on wide input signals. The T122/NL produces only one output pulse each time an input pulse exceeds the threshold, no matter how long the input signal remains above the threshold. The T122/NL also has an updating feature: if a second input threshold crossing occurs during the time interval of a previous output pulse, the output pulse gets updated, or

extended, for the preselected output pulse width or time beyond the most recent threshold crossing.

With four discriminators in each module, as many as 48 discriminators can be contained in a single bin. The result is an optimum combination of cost, performance, and logic flexibility.

### 3.2. INPUTS

Each of the four discriminator circuits in the T122/NL has a single signal input. When the input signal to any of the four discriminator circuits becomes more negative than its adjusted discrimination threshold, that circuit produces a NIM-standard fast logic signal through each of its three outputs.

A common gating or inhibiting signal can be fed into the T122/NL through the rear panel bin-to-module connector. The use of this signal is discussed in greater detail in Section 3.3.

### 3.3. CONTROLS

Each of the four discriminator circuits in the T122/NL has two front panel operation controls and four internal calibration controls. The two front panel controls, Width and Thresh, are recessed, screwdriver-adjusted potentiometers. They are provided to allow variations within design value limits of the output pulse width and the input threshold level respectively. The output signal width is continuously adjustable by means of the Width control throughout the range 5 to 800 nsec. The input threshold level is continuously adjustable by means of the Thresh control throughout the range  $-50$  mV to greater than  $-200$  mV, and a front panel monitoring jack provides a convenient means of checking the level at which the threshold has been set. Internal calibration controls Width Cal, Thresh Cal, and Thresh Norm, calibrate the range of the Width control and of the Thresh control. The fourth internal control, Reset, calibrates the level to which an input signal must decrease for the tunnel-diode discriminator to be reset to its low-voltage state.

The T122/NL is also equipped with a common gate amplifier for the four discriminators. The gating function is controlled by a locking toggle Bin Gate switch, located on the rear panel of the module, and is initiated by an external NIM-standard slow logic signal. However, for this feature to be utilized, the T122/NL must be installed in a bin that is equipped with logic lines or buses, as well as with power distribution lines or buses.

Because of the logic line required for the common gating feature and because the T122/NL uses  $\pm 6$ -V dc power, as well as power at the more common NIM module voltages, it is recommended that the T122/NL be installed in an EG&G/ORTEC M400 NIMBIN, which is equipped with, among others, the necessary logic line for the common gating feature and which delivers up to 8 A at  $\pm 6$  V dc, as well as power at the more common NIM module voltages.

### 3.4. OUTPUTS

Each of the four discriminator circuits produces a dual output signal (A and B) and a single back-terminated complementary output signal ( $\bar{A}$ ). Each dual output pair is driven by a 32-mA (twice NIM-standard logic level) current source.

### 3.5. APPLICATION EXAMPLES

The primary application of each section of the T122/NL is as a lower-level discriminator for fast logic signals of various amplitudes. The controlled output pulse width makes it useful in applications with slower-acting detectors, such as those made from sodium iodide. The updating feature makes it a particularly useful instrument in coincidence vetoing applications. The instrument can also be used to regenerate logic signals following transmission over cables long enough to cause significant losses in signal strength or waveform.

With four discriminators in each module, as many as 48 discriminators can be contained in a single NIM bin. The result is an optimum combination of cost, performance, and logic flexibility.

## 4. CIRCUIT DESCRIPTION

Refer to Fig. 4.1 and to the schematic and component layout drawings (Dwgs. 307022 and 307040) at the back of this manual.

### 4.1. GENERAL FUNCTION

The four direct-coupled discriminator circuits comprising the T122/NL Quad Updating Discriminator module are

identical in configuration, performance, and electrical characteristics; therefore the following block diagram description of a single circuit applies to all four.

The block diagram shown in Fig. 4.1 illustrates the functional relationships among the 10 circuit elements forming a single discriminator.

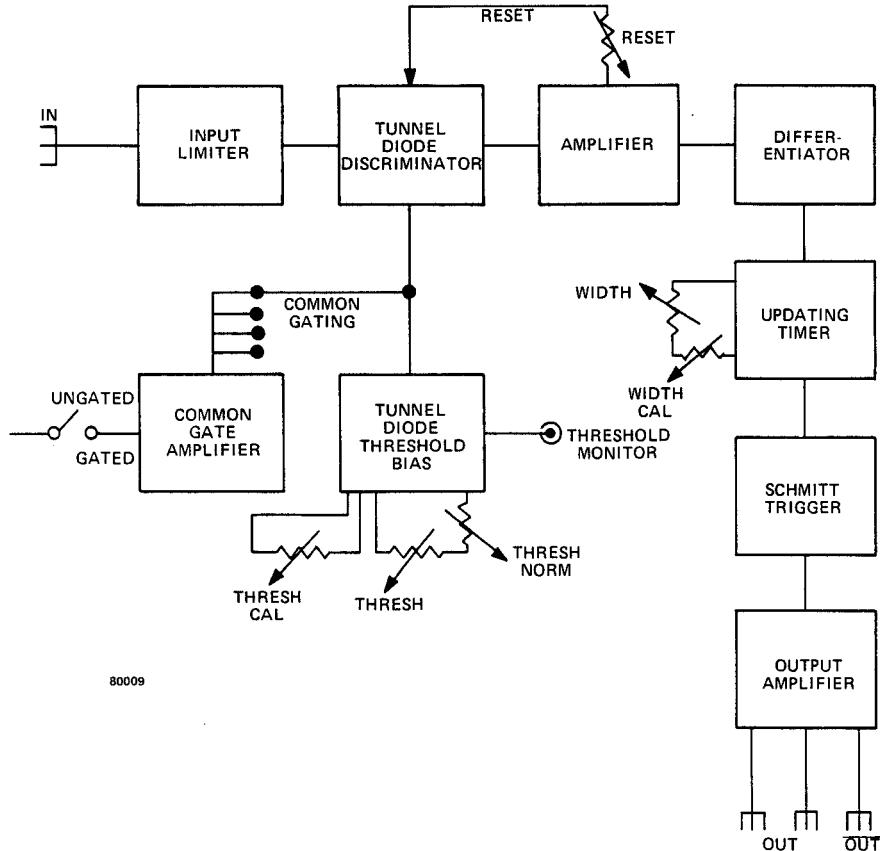

Fig. 4.1. Block Diagram of T122/NL Quad Updating Discriminator (Only One of the Four Shown).

In general, the T122/NL yields a NIM-standard fast logic output signal of adjusted width each time an input signal exceeds the adjusted threshold.

#### 4.2. BLOCK DIAGRAM DISCUSSION

The Input Limiter accepts a negative-going linear or digital signal as its input. When this input signal exceeds the preset threshold level, the Tunnel-Diode Discriminator switches to its high-voltage state. As the input signal current decreases, a second internally adjustable threshold is crossed, which causes the Tunnel-Diode Discriminator to revert to its low-voltage, or quiescent, state to await the next input signal. The discriminator switching action is first amplified, then differentiated, to produce a derivative of the threshold crossing. The derivative is a sharp, 1.5-nsec, negative-going pulse, which triggers the Updating Timer. Output pulse width is determined by the adjustable current source, which sets the discharge ramp for the updating capacitor in the Updating Timer. The design of the Updating Timer is such that each input signal occurring during the width of a given output pulse extends that output pulse one full output signal width from each point of input threshold crossing. The Updating Timer output is shaped at the leading and

trailing edges by a Schmitt Trigger, which in turn drives the Output Amplifier. The Output Amplifier further shapes the output to provide a stable NIM-standard output pulse.

When the T122/NL is used in conjunction with bin gating, the Common Gate Amplifier, when gated, drives the respective gate clamps to inhibit each of the four discriminator circuits in the module.

#### 4.3. CIRCUIT DISCUSSION

Transistors Q1 through Q3 and diodes D1 through D3 form the Input Limiter. With no signal at the input, the common base transistor Q1 is on and conducts 8 mA, which is determined by the current through R2. The base voltage of Q1 is maintained by the reference transistor Q2 so that the input open-circuit voltage never exceeds  $\pm 10$  mV. In the quiescent state, the emitter of Q1 is maintained slightly negative to forward-bias limiting diode D1. The forward bias on D1 is set at 360 mV so that, when an input signal exceeds  $-8$  mA and Q1 is turned off, limiting diode D1 is turned on to maintain the  $50\Omega$  terminating impedance, thereby minimizing signal reflection. In addition, diode D2

serves to protect the Input Limiter against large positive-going signals at the input.

Transistor Q3 is normally on and in the quiescent state conducts approximately 7 mA, which is the difference between the current at the collector of Q1 and the constant current through R7. Potentiometer R17 provides small adjustments of this current to allow for slight variations in tunnel-diode characteristics. When the current conducted by Q1 increases because of a positive input signal, diode D3 is turned on to limit the base bias on Q3, thereby preventing possible emitter breakdown.

The adjustable current source formed by transistor Q5 and potentiometers R15 and R10, together with the Q3 collector current, serves to bias the Tunnel-Diode Discriminator so that an additional 1 mA through the Q3 collector switches the device to its high-voltage state.

With the Bin Gate switch (S1) in the closed (Gated) position the presence of a Bin Gating signal activates the Common Gate Amplifier (Q19 and Q20), which in turn places transistor Q4 in saturation. The result is a current sink through the emitter of Q5 to ground, and this prevents tunnel diode D5 from switching to its high-voltage state, irrespective of input signal presence.

In the absence of an input signal, Tunnel-Diode Discriminator D5 is in its low-voltage state, so that transistor Q8 of the differential pair Q8-Q9 is on and Q9 is off. With a signal in excess of  $-50$  mV ( $-1$  mA in  $50\Omega$ ) present at the input the current conducted by Q1 will be reduced by 1 mA, and this causes a corresponding increase in the current conducted by Q3 to keep the current in R7 constant. The 1-mA increase at the collector of Q3 is sufficient to switch Tunnel-Diode Discriminator D5 to its high-voltage state. This action turns off Q8 and turns on transistors Q9 and Q6. The current conducted by Q6 is determined by potentiometer R16, which when correctly calibrated provides sufficient current at the collector of Q6 to reset Tunnel-Diode Discriminator D5 when the input signal drops below  $-25$  mV. Thus Tunnel-Diode Discriminator D5 in conjunction with transistors Q6 through Q9 in effect comprises a Schmitt Trigger that has an extremely sharp threshold with adjustable hysteresis.

When Tunnel-Diode Discriminator D5 is switched to its high-voltage state, the resulting change in collector current

between Q7 and Q9 is summed at differentiating inductor L4. The result is a 1.5-nsec pulse, which is the derivative of the input signal threshold crossing. The length of this pulse is determined by the differential time constant of L4 and R29. This sharp negative-going pulse turns on transistor Q10 of the current-switching pair Q10-Q11 and thereby causes Q11 to turn off sharply, providing a well-defined negative-going pulse to the base of updating emitter-follower Q13, turning it on. The base of Q13 is temperature-compensated by diodes D7 and D8.

Updating-emitter follower Q13 is normally on and conducts current at a level established by active current source Q12, which is adjusted by Width potentiometer R68 and the current supplied through R37. Zener diode D10 serves to vary the current exponentially through Q12, allowing the Width potentiometers to provide smoother control over output signal width.

The leading edge of the 1.5-nsec threshold derivative pulse turns off Q11, causing Q13 to discharge updating capacitor C16 rapidly. At the end of the threshold derivative pulse, updating emitter-follower Q13 is turned off by the Q10-Q11 pair switching back to the quiescent state. At that point updating capacitor C16 begins charging to its quiescent-state voltage at a rate determined by the current flowing out of active current source Q12. Transistor Q14 isolates the Schmitt Trigger Q15-Q16, from the updating capacitor. The use of a Schmitt Trigger at this point in the T122/NL circuit sharpens the relatively slow discharge time of updating capacitor C16 to effectively decrease the rise and fall times of the output pulse. Buffer transistor Q14 turns on normally off Q15 and turns off Q16. This action turns off normally on transistor Q17 in the Output Amplifier and turns on Q18, switching the 32-mA output current from Connector J2 and its back-terminator resistor, R58, to Connectors J3 and J4.

The Common Gate Amplifier is made up of the two normally off transistors, Q19 and Q20. With the Bin Gate toggle switch on the rear panel of the module in the Gated position, less than  $+2$  V will turn on transistor Q19. Turning on Q19 saturates Q20 and causes transistors Q4, Q104, Q204, and Q304 to be turned on, blocking the Tunnel-Diode Discriminator in each of the four discriminator circuits.

## 5. MAINTENANCE

### 5.1. PREVENTIVE MAINTENANCE

The only preventive maintenance required involves giving reasonable attention to mechanical details. Keep the signal connectors clean, and periodically remove the cover plates to inspect the interior of the module for excessive dust accumulation. Clean as often as required by local conditions (normally about once every 12 months).

### 5.2. CORRECTIVE MAINTENANCE

Corrective maintenance will generally be restricted to replacing defective components, such as resistors, capacitors, diodes, transistors, and IC's, to replacing missing hardware, and to tightening loose hardware. In tightening screws, nuts, etc., **do not** use excessive force.

When replacing components on a printed-circuit board, be sure that the board is not damaged by excessive heating. When unsoldering leads, grip the lead to be unsoldered with a tool that also acts as a heat sink. Heat the solder joint as little as possible while maintaining a steady pull on the

component lead to assure prompt removal of the lead. Use a solder puller to remove excess solder from the board. **Do not** redrill holes in the printed-circuit board. When the integrity of a plated-through hole is in doubt, solder the component lead on both sides of the board.

### 5.3. TEST POINTS AND VOLTAGES

Table 5.1 lists some test points within the circuitry of the module, together with the value of voltage to be found at each. Unless otherwise specified, all values in Table 5.1 are stated in volts dc. These voltages are not to be regarded as absolute values, but rather are typical of those found in a properly adjusted unit, operating with the nominal values of input voltages, with all outputs (yellow connectors) terminated in  $50\Omega$  impedances, with the proper input signals, with the Bin Gate switch in the open (Ungated) position, and with both the Width and Thresh controls set to the minimum or fully counterclockwise position. All measurements were made with a high-impedance digital voltmeter.

**Table 5.1. T122/NL Test Points and Voltages.**

## 6. CALIBRATION

The module must be removed from the bin for calibration. The most convenient method of performing the calibration involves the use of an extender cable or extender module (such as the EG&G/ORTEC EX100/N) to electrically connect the module to the bin buses while the module is outside the bin. Calibration of the T122/NL requires the adjustment of four potentiometers in each of the four discriminator circuits. Drawing 307040 shows a left-side elevation view of the printed-circuit board as assembled in the module. The front of the board is toward the right side of the drawing, and the top of the board is toward the top of the drawing. The threshold calibration potentiometers (R17, R117, R217, and R317, labeled "THRESH CAL" on Dwg. 307022) are located slightly to the rear from the center and near the bottom of that portion of the board that is allocated to each discriminator circuit. The threshold normalizing potentiometers (R10, R110, R210, and R310, labeled "THRESH NORM" on Dwg. 307022) are located at the bottom of that portion of the board that is allocated to each discriminator circuit and closer to the rear of the board than each corresponding threshold calibration potentiometer. The reset potentiometers (R16, R116, R216, and R316, labeled "RESET" on Dwg. 307022) are located in almost the center of that portion of the board that is allocated to each discriminator circuit. The width calibration potentiometers (R69, R169, R269, and R369, labeled "WIDTH CAL" on Dwg. 307022) are located at the top of that portion of the board that is allocated to each discriminator circuit and closer to the front of the board than each corresponding reset potentiometer. The calibration procedures listed below are for one discriminator

circuit only and must be repeated for each of the other three discriminator circuits.

### 6.1. REQUIRED EQUIPMENT

The following equipment is required for the performance of the T122/NL calibration procedure:

1. Sampling oscilloscope, Tektronix 661 or equivalent.
2. Fast-rise-time negative-going pulse generator, Hewlett-Packard 215A or equivalent.
3. High-impedance digital-readout voltmeter, Hewlett-Packard 3439A with Hewlett-Packard 3442A automatic ranging plug-in module or equivalent.
4. Bin-to-module extender cable or extender module, EG&G/ORTEC EX100/N or equivalent.

### 6.2. CALIBRATION PROCEDURE

Perform the following steps in the sequence listed:

1. With bin power turned off, remove the module from the bin and electrically reconnect it to the bin buses with the extender cable or extender module.
2. Place the rear panel Bin Gate Switch in the open (Ungated) position.

3. Turn on bin power, oscilloscope power, pulse generator power, and digital voltmeter power and allow the equipment to warm up for at least 5 min before proceeding beyond step 6.
4. Connect the digital voltmeter to the front panel threshold monitor jack for Section 1.
5. Turn the Section 1 front panel Thresh control fully counterclockwise (CCW).
6. Turn the Section 1 Thresh Cal control fully clockwise (CW).
7. Adjust the Section 1 Thresh Norm control for a reading of -500 mV on the digital voltmeter.
8. Turn the Section 1 Reset control fully CW.
9. Terminate all unused LEMO connectors in  $50\Omega$  impedances.
10. Set up the oscilloscope for external sweep triggering from the pulse generator.
11. Connect the output of the pulse generator to the Section 1 Input connector of the module.
12. Connect the Section 1 A connector on the module to the vertical input connector on the oscilloscope.
13. Set up the oscilloscope for a horizontal sweep time of 20 nsec per scale division and a vertical deflection of 200 mV per scale division.
14. Turn the Section 1 Thresh Cal control CCW until the output just begins to oscillate within the duration of the input signal.
15. With the output oscillating, turn the Section 1 Reset control CCW until the output oscillation just ceases. At this point no output pulse should be produced, the threshold should be approximately 10 mV, and the hysteresis should be >10 mV.
16. Increase the pulse generator output to -50 mV and turn the Section 1 Thresh Cal control CW. The circuit should produce an output pulse with only a slight turn of the control.
17. Continue turning the Section 1 Thresh Cal control CW until the output is half-triggered.
18. Turn the Section 1 front panel Width control fully CW.
19. Increase the pulse generator output amplitude to -100 mV.
20. Set up the oscilloscope for a horizontal sweep time of 100 nsec per scale division.
21. Adjust the Section 1 Width Cal control until the output pulse is 800 nsec wide.
22. Adjust the Section 1 front panel Width control until the output pulse is 10 nsec wide.
23. Repeat steps 4 through 22 for each of the other three discriminator circuits in the module.

*Set pulse to 10mV at 100 nsec  
width,*

## APPENDIX

## REPLACEABLE PARTS

## ORDERING INFORMATION

The Replaceable Parts List shown below contains information needed for ordering spare and/or replacement parts. Each listing indicates the reference designator number, the part number, a description of the component, and the part manufacturer and manufacturer's part number.

All inquiries concerning spare and/or replacement parts and all orders for same should include the model and serial numbers of the instruments involved and should be addressed to the Customer Service Department at 100 Midland Road, Oak Ridge, Tennessee 37830. The Manager of Customer Services can be reached by telephone at

(615) 482-4411. The minimum order for spare and/or replacement parts is \$25.00.

ORDERING INFORMATION  
FOR PARTS NOT LISTED

In order to facilitate the ordering of a part not listed below, the following information should be submitted to the Customer Service Department:

1. the instrument model number,
2. the instrument serial number,
3. a description of the part,
4. information as to the function and location of the part.

**BIN/MODULE CONNECTOR PIN ASSIGNMENTS  
FOR AEC STANDARD NUCLEAR INSTRUMENT MODULES  
PER TID-20893**

<b>Pin</b>	<b>Function</b>	<b>Pin</b>	<b>Function</b>
1	+3 volts	23	Reserved
2	-3 volts	24	Reserved
3	Spare Bus	25	Reserved
4	Reserved Bus	26	Spare
5	Coaxial	27	Spare
6	Coaxial	*28	+24 volts
7	Coaxial	*29	-24 volts
8	200 volts dc	30	Spare Bus
9	Spare	31	Spare
*10	+6 volts	32	Spare
*11	-6 volts	*33	115 volts ac (Hot)
12	Reserved Bus	*34	Power Return Ground
13	Spare	**35	Reset (Scaler)
14	Spare	**36	Gate
15	Reserved	**37	Reset (Auxiliary)
*16	+12 volts	38	Coaxial
*17	-12 volts	39	Coaxial
18	Spare Bus	40	Coaxial
19	Reserved Bus	*41	115 volts ac (Neut.)
20	Spare	*42	High Quality Ground
21	Spare	G	Ground Guide Pin
22	Reserved		

Pins marked (\*) are installed and wired in ORTEC 401A and 401B Modular System Bins.  
 Pins marked (\*) and (\*\*) are installed and wired in EG&G/ORTEC-HEP M250/N and M350/N NIMBINS.

The transistor types installed in your instrument may differ from those shown in the schematic diagram. In such cases, necessary replacements can be made with either the type shown in the diagram or the type actually used in the instrument.
