Alpha 5MeV 1.5atm D2

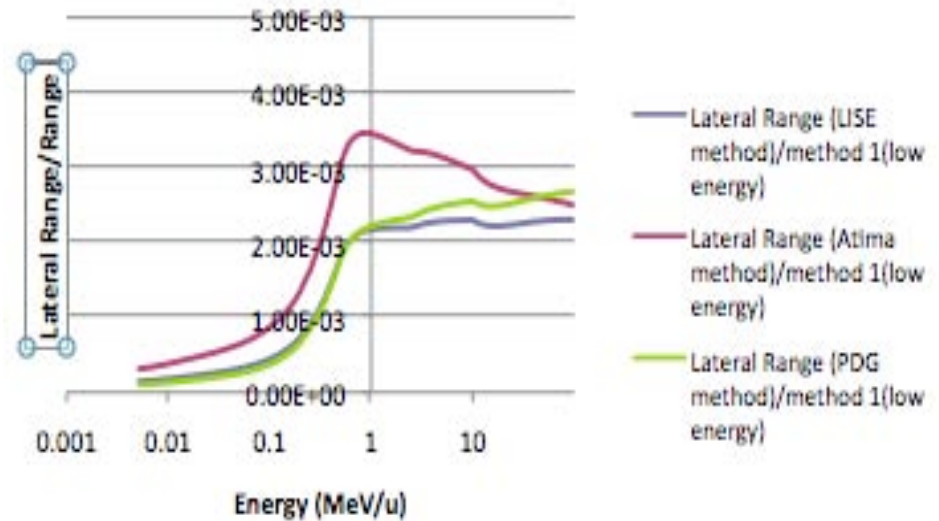

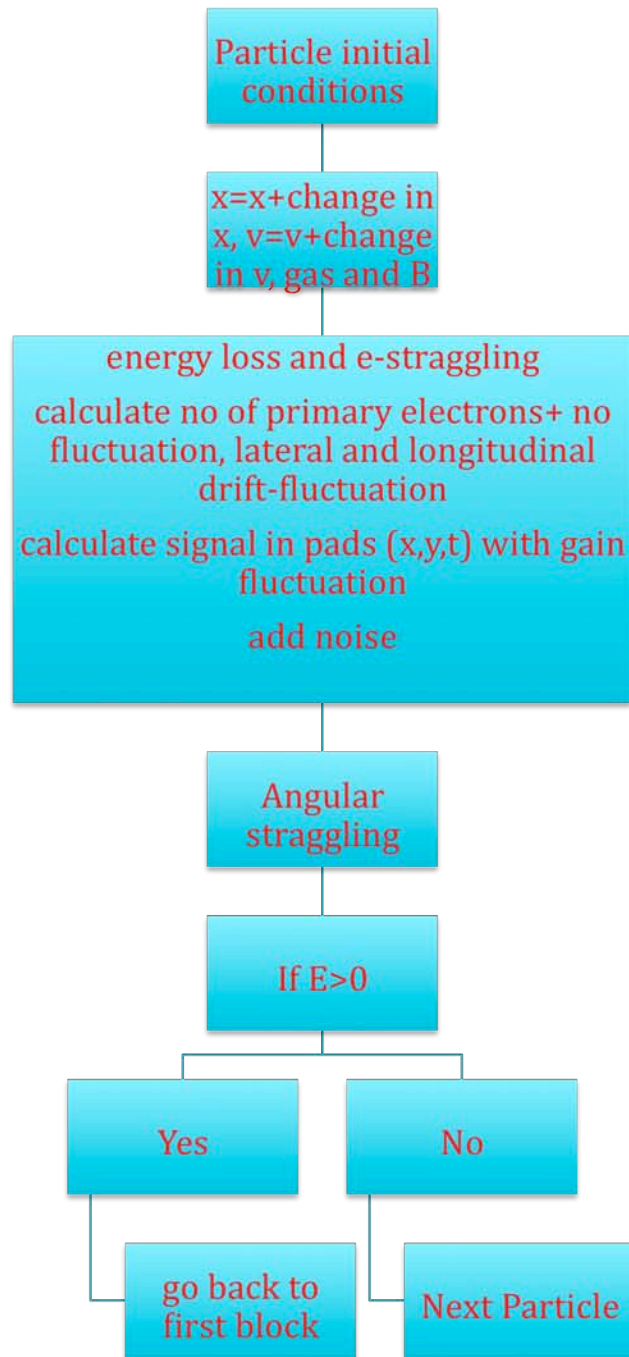

This is  $dR/R$  as a function energy [MeV] for Lise and Atima; the fine structure are different formula of range, the somewhat divergent curves at higher energy are for lise (upper ones) and Atima (lower ones). So one can conclude that above 100keV, the ratio is  $0.015 \pm 0.005$ .  
 From this one can plot  $dE/E$ , if E is determined by the range:

### Lateral Staggling vs. Energy

K.Tylor+O.Tarasov

Fig. 1. Schematic of a double GEM test cell designed for dispersion studies.

Fig. 4. Simulated pad response functions (PRF) compared to the measured PRFs for pads 29–31. The pad layout is shown in Fig. 5(a). The differences between the simulation and the measured PRFs are attributed to local variations in the system RC constant. Nevertheless, the simulated PRF is in good agreement with the data.

Resistance calculation:

NiCr  $1.08 \cdot 10^{-6} \Omega \text{m}$

With  $3 \mu$  strips  $0.1 \mu$  thick,

Every  $5 \mu$  length  $l$

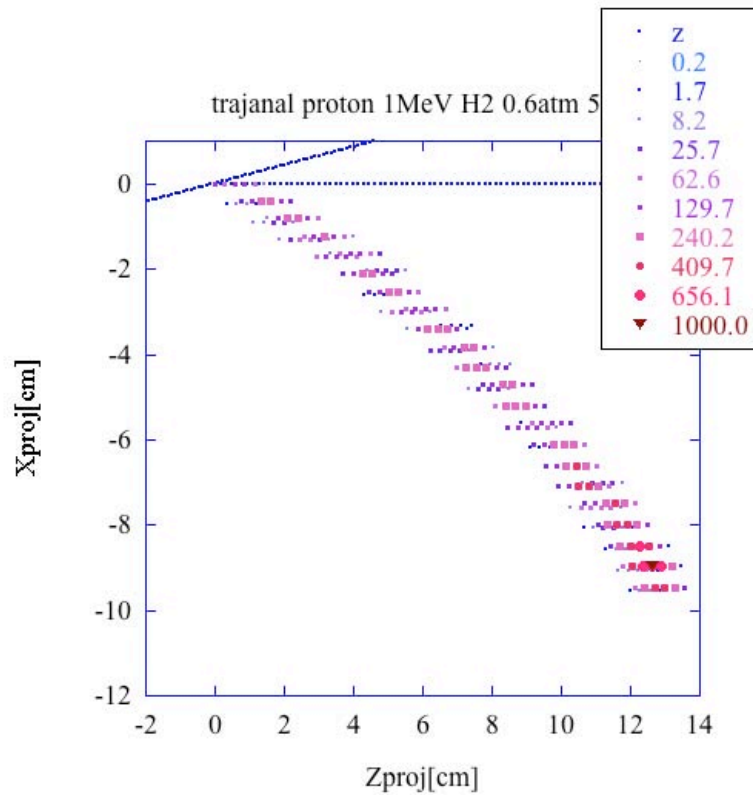

$$l = 0.49 \text{mm} \cdot .49 / 0.005 = 49 \text{mm}$$

$$R = 1.08 \cdot 10^{-6} \Omega \text{m} \cdot 0.049 \text{m} / (3 \cdot 10^{-6} \cdot 0.1 \cdot 10^{-6}) = 180 \text{k}\Omega$$

J.Yurkon + WM

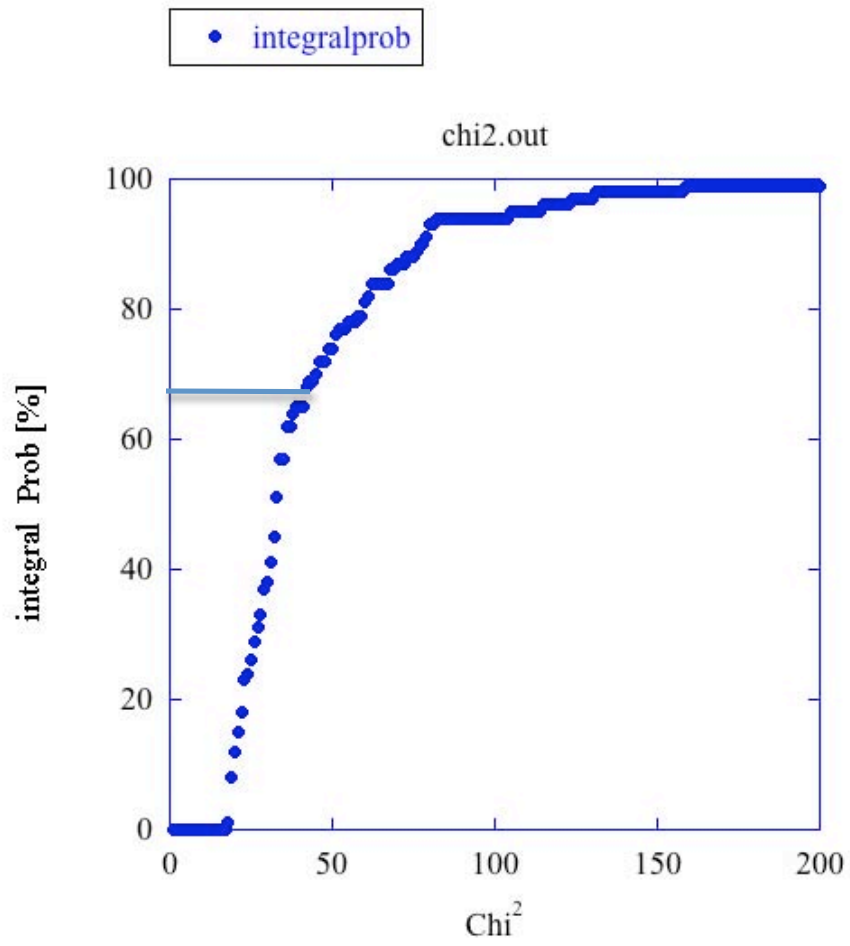

- To get a quantitative estimate of the resolution that may be achieved, for a given experimental condition and a given padstructure, the following procedure is adopted:
- 1) about 100 trajectories with fixed initial conditions are calculated
  - 2) the mean value of signal in the 3-dim x,y,z space (digitalized following padstructure and time buckets)
  - 3) the chi2 defined as the deviation of the signal for an individual trajectory with varying initial conditions from the mean value
